In recent years, due to a development of information communications technology (IT), a network has been widely used and various types of information and communication services, such as Internet service, the World Wide Web (WWW) service, mail, and electronic commerce (EC), are provided through the network. As a result, usage of the network is increased. Thus, the number of subscribers to access the network is rapidly increased. As shown in FIG. 1, a conventional communication network has a structure of a client/server architecture or a structure of an ad-hoc architecture. The client/server architecture is provided as a communication network among computer terminals. The client/server architecture is connected to a local area network (LAN) or an intranet through a gateway. Also, the ad-hoc architecture is provided by using only mobile terminals or user devices without the use of a gateway. In the conventional client/server architecture as shown in FIG. 1, when communication services are provided from a server to a client, there are problems in that a communication service cannot be provided if the server is not connected to the network, and a service provider cannot manage the client/server architecture. Also, in order to provide the services, it is necessary to set a line for connection between the client and the server, and a large number of lines are necessary in a large communication network. Accordingly, there are problems in that a communication cost is increased and the network resources are wasted. Further, it is difficult to cope with a dynamic change of the network, so that the maintenance cost and a development cost are increased. In the ad-hoc architecture, since the ad-hoc network is set by the mobile
