The purpose of this study was to assess the availability of and policies for pregnant and breastfeeding women in the workplace and to determine the association of having a policy and reporting workplace exposure to environmental tobacco smoke (ETS) during pregnancy. Data were collected through an Internet-based survey and telephone interviews of business and government officials in Connecticut. A total of 100 businesses and government agencies in Connecticut were contacted by telephone and Internet. As a result of the telephone survey, 60% of businesses and 64% of government agencies had an official policy for pregnant women. Of the business and government agencies that responded to the survey, 81% reported having an official policy for pregnant women and 63% reported having an official policy for breastfeeding women. At least one business or government agency had no policy for pregnant or breastfeeding women. Of the businesses that responded to the survey, 32% of businesses had an ETS exposure limit of 0, 18% of businesses had an ETS exposure limit of 1-6, 48% of businesses had an ETS exposure limit of 7-9, and 8% of businesses had an ETS exposure limit of 10. ETS exposure was higher among those that had a policy for pregnant or breastfeeding women and those that did not. The results of this study are useful for institutions that are developing policies for pregnant and breastfeeding women in the workplace. Future policy development and enforcement should consider the recommendations of this study to ensure that pregnant and breastfeeding women are protected from ETS in the workplace.[The value of genotyping in the epidemiological study of cancer]. In current time, more than 70% of human cancers are attributed to environmental factors (diet, lifestyle, exposure to environmental carcinogens). The genetic risk factors have been suspected in familial aggregation of cancers, but their role has never been formally proven. Mutations in known cancer genes are a major cause of familial cancer syndromes. Identification of genes involved in the carcinogenesis process has led to the development of tools for molecular epidemiology of cancer. The main applications are for genotyping of high-risk populations, for familial searching for inherited cancers and for the identification of causes of cancer in unexplained situations. The most significant of these new applications is the assessment of the influence of genetic background on risk of developing cancer. For these aims, several polymorphisms in cancer susceptibility genes are suitable to genetic testing
