Cirrhosis is a well-established risk factor for colorectal neoplasia. This study was designed to determine whether DNA extracted from the stomach or stool could be used to study the relationship between cirrhosis and colorectal neoplasia. Thirty-five patients undergoing routine colonoscopy were randomly selected from a prospective cohort. Stomach and stool samples were simultaneously collected from each patient at the same time as colonoscopy. The DNA from the stomach and stool was extracted and examined for evidence of microsatellite alterations using an 18S rDNA microsatellite panel. Sixty-two percent of patients with gastric ulcer, 17% of patients with gastric cancer, and 6% of patients with gastric adenoma had an altered stomach-derived microsatellite profile. The sensitivity of the stomach to detect microsatellite instability (MSI) was 100% for gastric cancer and for adenoma, whereas the specificity of the stomach was 96% (13/14) for gastric cancer and 73% (16/22) for gastric adenoma. The rate of microsatellite alterations in stool was significantly lower than that in the stomach. The stomach is the most effective tissue to use for studying the relationship between cirrhosis and colorectal neoplasia. In contrast, stool samples are not suitable for studying this relationship.Q: php copy only certain values to new array I'm trying to copy specific keys and values from an array to a new array using php.
