Resolution of the molecular bases of metachromatic leukodystrophy in cultured skin fibroblasts by genetic complementation and linkage studies. Using fibroblast lines from three patients with metachromatic leukodystrophy (MLD), two types of complementation studies on enzymatic activities were performed. Kinetic analyses on hexosaminidase activity and electron microscopic (EM) studies on myelin particles were indicative of a partial enzymatic defect. However, when levels of mRNA of six enzymes related to heparin sulphate, nonsulphated glycolipids, and sulfatides were compared in fibroblasts from patients and controls, no differences were found. Linkage analysis with enzymes polymorphic for the spinocerebellar degeneration-1 (SCD-1) locus, the locus which has been associated with MLD, showed that three spinocerebellar families were doubly homozygous at this locus. Addition of human MLD fibroblasts to embryonic neural tubes revealed a non-suppressed expression of these three enzymes. Subsequent analyses on the spinocerebellar family, which was found to be doubly homozygous, confirmed the linkage of these genes to the SCD-1 locus. Since it is known that SCD-1 is not transcribed in fibroblasts, these findings strongly suggest that these individuals are homozygous at both the SCD-1 and a yet unknown, second defective locus.

Q: How to determine the output resistance of an OpAmp? I'm currently trying to determine the output resistance (R_{out}) of an OpAmp (following: How to determine the open-loop gain of a differential amplifier?). However, I'm unable to determine the R_{out} . I've implemented the following circuit: simulate this circuit – Schematic created using CircuitLab Assuming that the input differential signal V_+ and V_- is the input voltage, that is V_{in} , and that $V_{in} > 0$, the opAmp's non-inverting input is V_{in} , and that OpAmp's inverting input is 0, we have: $V_+ = V_{in}$ $V_- = 0$ $V_{out} = V_+ * (1 + \frac{R_2}{R_1})$ $V_{out} = V_{in} * (1 + \frac{R_2}{R_1})$
