You can get MSSQL-MySQL Sync Crack For Windows for Mac OS X and Windows right now. This invention relates to analog-to-digital converters (A/D converters). A/D converters are commonly used to convert an analog signal to a digital signal for processing. The A/D converter generates a digital output based on the analog input signal. In some applications a high analog input signal can result in a digital output having a high value. This can cause increased power consumption and increased heat, possibly leading to performance and/or reliability problems. Some A/D converters compensate for large analog input signals by allowing extra time for the conversion process. The conversion process is performed by a current source, where a time period is used to charge a capacitor for a time period. During this time period, the current source is enabled until the capacitor is charged to a reference voltage. Once the capacitor is charged to the reference voltage, the current source is disabled. The time period is related to the analog input signal, and is often half the period of the reference voltage. This leads to an A/D converter with a relatively slow conversion rate. Accordingly, there is a need in the art to provide a fast A/D converter for large analog input signals. The above-mentioned need is met by a non-volatile A/D converter with a fast conversion rate. The non-volatile A/D converter includes a current source, a capacitor, and a reference voltage source. The current source generates a current, and the capacitor is coupled to the reference voltage source. The capacitor is connected to the current source, and is charged in response to the analog input signal. The capacitor is in parallel with the reference voltage source. The reference voltage source generates the reference voltage. The reference voltage source includes a comparator, and the reference voltage is a comparison voltage. The comparator compares the charge level of the capacitor to the comparison voltage. The comparator generates a first signal for the current source upon receipt of the comparison voltage and the charge level. The first signal causes the current source to generate a decreased current. The comparator generates a second signal for the current source upon receipt of the charge level and the reference voltage. The second signal causes the current source to generate a constant current. By operating the current
